## Must know

---

- **Big O** describes the **worst-case** growth of **time** (operations) or **space** (memory) as input size **n** grows. Drop constants and lower-order terms:  $4n^2 + 200n + 9 \rightarrow O(n^2)$  (dominant term wins).
- Growth order (best  $\rightarrow$  worst): **O(1)** constant  $\rightarrow$  **O(log n)** logarithmic  $\rightarrow$  **O(n)** linear  $\rightarrow$  **O(n log n)** linearithmic  $\rightarrow$  **O(n<sup>2</sup>)** polynomial/quadratic  $\rightarrow$  **O(2<sup>n</sup>)** exponential. **Tractable** = polynomial time or better; **intractable** = exponential or worse.
- **Linear search** — **O(n)**. Checks each element in turn; works on **unsorted** data. Use when the list is small or unsorted.
- **Binary search** — **O(log n)**. Checks the middle of a **sorted** list and discards the half that cannot contain the target. **Requires sorted data** — quote this precondition. Use for large, sorted lists.
- **Bubble sort** — **O(n<sup>2</sup>)**. Repeatedly compares adjacent pairs and swaps; largest "bubbles" to the end each pass. Best case **O(n)** only **with a swap flag** on already-sorted data. Simple to code but slow — use only for tiny lists.
- **Insertion sort** — **O(n<sup>2</sup>)**. Builds a sorted front section, inserting each next item into place. Best case **O(n)** on nearly-sorted data. Good for small or nearly-sorted lists.
- **Merge sort** — **O(n log n) in all cases**. Divide-and-conquer: split in half recursively, then merge sorted sublists. **Guaranteed O(n log n)** but needs **O(n) extra space**. Use when consistent performance matters.
- **Quick sort** — **O(n log n) average, O(n<sup>2</sup>) worst**. Divide-and-conquer: pick a **pivot**, partition (smaller left / larger right), recursively sort each side. Worst case with a poor pivot (e.g. already-sorted data). Fast in practice, in-place (**O(log n)** space).
- **Stack (LIFO)** and **queue (FIFO)** operations are **O(1)**. **DFS uses a stack** (or recursion); **BFS uses a queue**.
- **Tree traversals**: **pre-order** (Node  $\rightarrow$  Left  $\rightarrow$  Right, copy a tree), **in-order** (Left  $\rightarrow$  Node  $\rightarrow$  Right, outputs a **BST in ascending order**), **post-order** (Left  $\rightarrow$  Right  $\rightarrow$  Node, delete a tree / evaluate RPN).
- **Path-finding**: Dijkstra uses **g(n)** only (uninformed, shortest path to all nodes); **A\*** uses **f(n) = g(n) + h(n)**, adding an **admissible heuristic** h(n) estimating remaining cost to the goal — it directs the search and usually explores fewer nodes to reach a single goal.

## Key terms

| Term                     | Definition                                                                             |
|--------------------------|----------------------------------------------------------------------------------------|
| Algorithm                | A precise, finite sequence of steps to solve a problem                                 |
| Big O notation           | How an algorithm's time/space requirement grows with input size $n$ (worst case)       |
| Time complexity          | Number of operations as a function of input size                                       |
| Space complexity         | Memory required as a function of input size                                            |
| Tractable / Intractable  | Solvable in polynomial time or better / only exponential or worse                      |
| Divide and conquer       | Break into subproblems, solve, then combine (merge/quick sort, binary search)          |
| Pivot                    | The element chosen in quick sort to partition the list                                 |
| Stable sort              | Preserves the relative order of equal elements                                         |
| Heuristic                | A rule-of-thumb estimate; in $A^*$ , the estimate $h(n)$ of remaining cost to the goal |
| Admissible heuristic     | One that never overestimates the true remaining cost → guarantees $A^*$ optimality     |
| Traversal                | Visiting every node of a structure in a defined order                                  |
| $g(n)$ / $h(n)$ / $f(n)$ | Actual cost so far / heuristic estimate to goal / estimated total ( $g + h$ )          |

## Worked example / how to — Big O comparison of the standard algorithms (double-checked)

| Algorithm      | Best          | Average       | Worst                      | Space                         | Stable? | Precondition               |
|----------------|---------------|---------------|----------------------------|-------------------------------|---------|----------------------------|
| Linear search  | $O(1)$        | $O(n)$        | $O(n)$                     | $O(1)$                        | —       | none (works on unsorted)   |
| Binary search  | $O(1)$        | $O(\log n)$   | $O(\log n)$                | $O(1)$ iter / $O(\log n)$ rec | —       | <b>list must be sorted</b> |
| Bubble sort    | $O(n)^*$      | $O(n^2)$      | $O(n^2)$                   | $O(1)$                        | Yes     | —                          |
| Insertion sort | $O(n)$        | $O(n^2)$      | $O(n^2)$                   | $O(1)$                        | Yes     | —                          |
| Merge sort     | $O(n \log n)$ | $O(n \log n)$ | $O(n \log n)$              | <b><math>O(n)</math></b>      | Yes     | —                          |
| Quick sort     | $O(n \log n)$ | $O(n \log n)$ | <b><math>O(n^2)</math></b> | $O(\log n)$                   | No      | —                          |

\* Bubble best case  $O(n)$  only **with a swap flag** on already-sorted data; otherwise  $O(n^2)$ .

Key contrasts: **binary search beats linear search** ( $O(\log n)$  vs  $O(n)$ ) but needs sorted data. **Merge sort guarantees  $O(n \log n)$**  at the cost of  **$O(n)$  extra space**, whereas **quick sort** is usually as fast and in-place but degrades to  **$O(n^2)$**  with a poor pivot — a classic time-vs-space and average-vs-worst trade-off.

## Exam tips

- **Binary search is  $O(\log n)$  and REQUIRES sorted data** — always state the precondition.
- **Always justify** a Big O, e.g. " $O(n^2)$  because the nested loop makes up to  $n$  comparisons for each of  $n$  passes."
- **Quick sort worst case is  $O(n^2)$ ; merge sort guarantees  $O(n \log n)$  but uses  $O(n)$  extra space** — name the trade-off.

- **DFS uses a stack; BFS uses a queue, and in-order traversal of a BST outputs values in ascending order** — do not mix these up.
